Abstract

Objective: To map the use of the peer support implementation strategy in the Primary Health Care (PHC) setting through a scoping review of randomized clinical trials, reporting its results in health and the implementation process.

Methods: The development of this scoping review was guided by the Joanna Briggs Institute (JBI) methodology. Scopus, Scielo, PubMed, Web of Science databases and gray literature were searched. Articles published in the seven previous years (2017 to 2023) related to the Primary Health Care setting, and reporting health outcomes and at least one implementation outcome were selected.

Results: Initially, 259 articles were mapped. After removing duplicates and applying the criteria, 15 were selected. The health problems addressed were mostly related to the human immunodeficiency virus (HIV) and other sexually transmitted infections (STIs) and chronic non-communicable diseases. The main implementation outcomes presented involved adoption, acceptability, reach, fidelity, feasibility, sustainability and appropriateness. Few studies adopted theoretical implementation frameworks to conduct and report the findings.

Conclusion: The peer support strategy has been used in some PHC settings, with mapping that covers areas such as mental health, STIs and chronic non-communicable diseases. Positive health impacts included viral suppression of HIV, significant reduction in systolic blood pressure, and a decrease in the amount of alcohol consumed. However, studies analyzing effectiveness in other PHC scenarios are still lacking, especially regarding fidelity, feasibility, sustainability, appropriateness and cost.

Resumo

Objetivo: Este estudo teve como objetivo mapear, por meio de uma revisão de escopo de ensaios clínicos randomizados, a utilização da estratégia de implementação do apoio por pares em contextos da Atenção Primária à Saúde (APS), para tanto, relatando seus resultados na saúde e no processo de implementação.

Resultados: Inicialmente, foram mapeados 259 artigos e, após remoção de duplicatas e aplicação dos critérios, 15 foram selecionados. Os problemas de saúde abordados foram, em sua maioria, relacionados ao vírus da imunodeficiência humana (HIV) e outras infecções sexualmente transmissíveis e doenças crônicas não transmissíveis. Os principais desfechos de implementação apresentados envolveram adoção, aceitabilidade,
Introduction

Peer support is the implementation strategy defined as a transfer of common experiences by individuals belonging to the same territory or facing the same social, cultural or health challenges. Implementation strategies point to the methodology for changing healthcare practices and seek to improve aspects related to adoption, implementation and sustainability.\(^{(1)}\) In the taxonomy of implementation strategies proposed by Powell et al. (2015),\(^{(2)}\) peer support recruits, assigns and trains for leadership.

In this context, the “peer” aims to support and strengthen the other’s resilience through knowledge gained from shared experience.\(^{(3)}\) In another definition, the peer support strategy refers to the use of non-professionals who are assigned to the position of “leaders” and work by technically and emotionally helping people with social weaknesses or certain illnesses to adopt, transform and/or strengthen their health habits.\(^{(4)}\) Thus, peer support has been expanding in interventions that involve the health of the community, while its adoption is solidified in different health scenarios, such as chronic diseases, sexual and reproductive health and mental health.\(^{(5)}\) This strategy assigns groups with similar problems the role of providing support to individuals with coping difficulties.

Peer support started as a patient-centered care tool, aiming to improve the prevention of health problems and reduce the costs of disease interventions. There are studies showing the benefits of peer support in combating cardiovascular diseases in relation to a reduction in systolic pressure, decrease in waist circumference and weight loss.\(^{(6)}\)

The use of peer support can play a decisive role in the recovery of patients with mental illness, and help with early diagnosis, coping with mental illness, autism spectrum disorder and the socialization of these individuals.\(^{(7,8)}\) Peer support has also been important in accepting and accessing information about the prevention of HIV infection.\(^{(9)}\)

In the Primary Health Care (PHC) setting, this implementation strategy can act as a bridge between the health professional/service and interventions involving the health of communities, thereby assisting in care in health units, as support leaders can help with engaging users and the community in preventive behaviors.\(^{(10)}\) Currently, several other documented peer support programs have obtained
excellent results in improving the quality of life and clinical conditions of patients who participated in this intervention modality – which is considered innovative for health services.\(^{(6)}\)

Implementation strategies are crucial for the successful implementation of health policies and interventions, especially in PHC. Although peer support is a promising strategy to optimize the implementation of health interventions in PHC, it is necessary to better understand how this approach can be adapted to different care realities, integrated into the health system and about its costs and benefits in comparison to other implementation strategies.\(^{(11)}\) Knowing the randomized clinical trials that used the peer implementation strategy may be a way to elucidate a promising field of research with the aim to facilitate the process of implementing interventions in public health and understand potential barriers and facilitators of this public health strategy. Understanding knowledge gaps for the application of this implementation technique would also be necessary to strengthen PHC in its varied settings.

The aim of this study was to map the use of the peer support implementation strategy in the PHC setting through a scoping review of randomized clinical trials and report its outcomes in health and the implementation process.

### Methods

The peer support implementation strategy in health-care is investigated in this scoping review study. The Joanna Briggs Institute (JBI) methodology was used as a guide for the review, seeking to map the implementation outcomes evaluated in studies in which the peer support strategy was implemented in PHC.\(^{(12)}\) Since this is a scoping review, the study did not aim to evaluate the quality of clinical trials, but rather to specify data that supports and enables the understanding of knowledge gaps relevant to the topic.

Data collection was guided by the Participants (Population), Concept and Context (PCC) strategy.\(^{(13)}\) The population was represented by studies of adolescents, adults or older adults who had participated in clinical trials; the concept involved peer support; and the context was related to PHC. The research question was: “What are the results achieved in health and in implementation with the peer support strategy in Primary Health Care?”.

The searches were carried out in four databases: PubMed, Web of Science, SciELO and Scopus. The Catalog of Theses and Dissertations from the Coordination for the Improvement of Higher Education Personnel (CAPES) was used for the gray literature (dissertations and theses). The electronic search strategy was carried out using keywords related to (peer influence or peer support or peer) AND (implementation science or implementation or implementation outcomes or hybrid designs) AND (health or health services research or chronic health) AND (primary health care or Family health strategy) AND (randomized clinical trials). The search was carried out from January 2017 to April 2023, limited to articles that met the eligibility criteria: a) Results of randomized clinical trials that evaluated implementation by peers; b) Having evaluated at least one health outcome; c) Reporting at least one implementation outcome.

The selection of articles was carried out as follows: in the first stage, the search strategy was developed by combining the already mentioned descriptors used on the databases. In the second stage, filters were applied (clinical trial; English and Portuguese languages; publication date from 2017 to 2023) and the retrieved articles were initially stored in the EndNote\(^\text{®}\) bibliography manager software, from which duplicates were removed automatically and, later, manually. At this point, the titles and abstracts were read with the aim to assess if the articles corresponded to the research question. Finally, the pre-selected articles were read in full, identifying more precisely their relevance to the review and if inclusion and exclusion criteria were met. At this last stage, relevant data for analysis were extracted.

Reviewers independently mapped the data, discussed the results, and continually updated the data graph form in an interactive process. Three reviewers, RAB, JAVC and JRL, were involved in the screen-
ing process and inconsistencies were discussed in advance.

The study protocol was published on the protocols.io platform (https://www.protocols.io/private/0664E5E62A91807BE599BD530819A602).

The following data were extracted from the articles and organized in a Microsoft Excel 2010 table: theme, title, author, year of publication, location, type of study, objective of the study, description of the intervention, health outcome, in-service outcome and implementation outcome.

The definitions provided by Lorthios-Guilledroit et al. (2018) were used to determine the outcomes examined in the studies, as implementation outcomes were not always clearly stated in the articles. Eight implementation outcomes among all sought were considered more important, namely: 1) Acceptability: perception among users that the intervention is acceptable; 2) Adoption: intention, initial decision or action to try to adopt a new intervention by participating users; 3) Appropriateness: perception of the relevance of the intervention in a particular context or for a specific audience; 4) Feasibility: extent to which a new intervention can be carried out in a context or organization; 5) Fidelity: degree to which the intervention is delivered as initially planned without the need for adaptation; 6) Implementation Cost: incremental (and total) cost of the implementation strategy; 7) Coverage/Reach: degree to which the eligible population to receive the intervention actually receives it; 8) Sustainability: extent to which an intervention is maintained and institutionalized in a given context.

Results

The search strategy initially used resulted in 259 articles; 148 on PubMed, 71 on Web of Science, 40 on Scopus and zero on SciELO and the Capes platform. After analyzing duplicates, 35 were excluded, resulting in 224 articles. After reading the title and abstract, 64 were selected for full reading and 15 were selected for analysis, as they met all inclusion criteria (Figure 1).

For the most part, the addressed health problems were related to HIV and other sexually transmitted infections (STIs) and chronic non-communicable diseases, which are sensitive topics to the operating context of PHC. The main implementation outcomes presented involved adoption, acceptability, reach, fidelity, feasibility, sustainability and appropriateness. No study evaluated the cost. In five out of the 15 articles selected, a theoretical framework was used in the development of the study, including: RE-AIM (n=2), RE-AIM and PIPE (n=2) and Proctor (n=1), while in ten studies, a theoretical implementation framework was not used to support the study. In chart 1, health outcomes were concentrated in six major themes: mental health, infectious diseases/STIs, chronic non-communicable diseases, health education, neglected diseases and one involved health promotion.

Discussion

Three main points stood out among the main findings of this scoping review. First, when the peer support strategy was evaluated through clinical trials, it has promoted some significant results in health outcomes such as chronic diseases and STIs. Second, gaps have been observed in the use of peer support, such as the constant absence of theoretical implementation frameworks to support the study. Third, there were few reports on fidelity outcomes, an essential outcome to assess if interventions are being conducted as planned, as well as few randomized clinical studies addressing peer support in the current PHC setting. The peer support strategy is not a new intervention methodology within PHC and presents barriers and facilitators for its clinical practice.

Although the peer support strategy is more consolidated in the field of mental health, only one article on this topic was found in this review, reporting the threat to life (self-mutilation) as the most common serious adverse event. The primary outcome was psychiatric readmission 12 months...
after discharge. Despite showing good adoption, health outcomes did not reveal significant effects; the adjusted risk ratio for readmission was 0.97 (95%CI 0.82; 1.14) and the adjusted odds ratio for readmission was 0.93 (95%CI 0.66; 1.30). The unadjusted risk difference was 0.03 (95% CI −0.11; 0.05) in favor of the peer support group, showing no significant effects between the control group and the intervention arm.

In recent years, peer support in the PHC setting has been more used to address STIs, which is defined as an important complement to medical treatments in the area. Implementation in the field of STIs /HIV proved to be statistically successful, in line with the literature, bringing viral suppression as health outcomes, such as the study addressing puerperal women with greater adoption of the intervention to the detriment of those with lower adoption, and the implementation outcome related to positive effects. Acquired Immune Deficiency Syndrome continues to be an important public health problem, and the results of these randomized clinical trials can support positive strategies for HIV viral suppression in PHC.

Studies on Diabetes Mellitus and Systemic Arterial Hypertension were conducted in the context of chronic non-communicable diseases and reported positive outcomes. The interventions brought the health outcomes of a significant drop in systolic blood pressure and lower amount of alcohol consumed in the intervention groups compared to control groups. The implementation outcomes more discussed in this topic were adoption, acceptability, reach and fidelity. The study that evaluated implementation costs pointed to a relatively low-cost intervention; U$ 22.5 per patient per year.

Neglected diseases are important topics for PHC. Tuberculosis was the subject of two randomized clinical studies using peer support to strengthen adherence to disease treatment. Even using the RE-AIM theoretical framework, none of the...

studies obtained a significant statistical difference, thus revealing implementation outcomes with low levels of reach and adoption,\textsuperscript{(23, 24)} and in both studies, the outcome of implementation fidelity was not reported.

Education and health promotion, which are primary policies in PHC, were addressed in randomized studies that did not use theoretical implementation frameworks, possibly explaining the inconclusive or non-significant health outcomes found.\textsuperscript{(22,27,28)} The studies reported as outcomes of implementation, the adoption, effect,\textsuperscript{(22)} acceptability\textsuperscript{(27)} and fidelity of the intervention.\textsuperscript{(28)} The selection of only 15 studies showed the little production of randomized clinical trials using the peer support strategy in PHC in recent years.

Most of the included studies had gaps in the field of implementation science, such as the lack of reporting of the theoretical frameworks used.\textsuperscript{(14,15,19,22,28)} Furthermore, the lack of statistical significance in the results related to the health outcomes analyzed can be attributed, in part, to the limited consideration of crucial aspects of implementation, such as sustainability, fidelity, reach and appropriateness.\textsuperscript{(14)} These results can also be explained by the lack of understanding of the determinants and mechanisms that act as obstacles and facilitators in implementing peer support.

The positive findings described can support the implementation of the strategy within the scope of Brazilian PHC, as the national scientific production reporting the use of peer support by health professionals in the country is scarce. Based on the results of the studies in this review,\textsuperscript{(15,16,19,21,26)} it would be possible to strengthen the successful policy to combat STIs\textsuperscript{(35)} and combat chronic non-communicable diseases.\textsuperscript{(36)} As shown, this can be achieved with nursing involvement in collaborative practices with the entire family health team.\textsuperscript{(37)}

The gap in knowledge of theoretical frameworks and interventions in implementation science can interfere with the analysis of outcomes, often presenting underestimated results or lacking important data for further clarification on certain interventions. Retrieving only clinical studies may have limited the exploration of other themes in which peer support is being used. However, it was possible to assess the performance of the intervention compared to groups without intervention, or compared with the intervention that was usually carried out. Despite its relevance and acceptance by the population, significant knowledge gaps still persist, especially regarding the application of theoretical implementation frameworks, the analysis of their public health outcomes and how to assess the fidelity of these interventions.

In this context, new studies could deepen the understanding of how such strategies are implemented, which theoretical frameworks support these practices and, mainly, what is the real impact achieved through peer support.

**Conclusion**

The peer support strategy has been used in some PHC settings with the mapping that covers areas such as mental health, STIs and chronic non-communicable diseases. Positive health impacts included HIV viral suppression in puerperal women who adopted the intervention, significant reduction in systolic blood pressure, and a decrease in the amount of alcohol consumed in the intervention groups. However, there is still a lack of studies to analyze the effectiveness in other PHC scenarios, especially regarding fidelity, feasibility, sustainability, appropriateness and cost.
